

# pan-Canadian FHIR Exchange (CA:FeX) Interoperability Specifications

Version: 0.1

Type: Draft

Release Date: January 28, 2022

📥 Canada Health Infoway

# Table of Contents

| 1     | CA:FeX Interoperability Specifications  | 5   |
|-------|---|-----|
| 1.1   | Introduction  | 5   |
| 1.2   | Intended Audience   | 5   |
| 1.3   | Purpose   | 5   |
| 1.4   | Glossary of Terms and Acronyms  | 6   |
| 1.5   | Preface   | .10 |
| 1.5.1 | Context   | 11  |
| 1.5.2 | Introduction to IHE   | 11  |
|       | How to Read This Document   |     |
| 1.5.4 | Document Conventions  | 12  |
| 1.5.5 | Requirements Language   | 13  |
| 1.5.6 | Methodology   | 13  |
| 1.5.7 | Introduction to a Use-Case Driven Approach  | 13  |
| 1.5.8 | Release Cycle   | 13  |
| 1.6   | CA:FeX Use Case Overview  | .14 |
| 1.6.1 | Use Case Overview   | 14  |
| 1.6.2 | In-Scope  | 14  |
| 1.6.3 | Use Case Actors and Services  | 14  |
| 1.6.4 | Design Constraints & Assumptions  | 15  |
| 1.7   | Core Interoperability Specification Requirements  | .16 |
| 1.7.1 | Actor Mapping to Interoperability Specification   | 16  |
| 1.7.2 | Table 1 Interoperability Conformance Requirements for Use Case 1: Create and Submit Document  | 17  |
| 1.7.3 | Table 2 Interoperability Conformance Requirements for Use Case 2: Query and Retrieve Document | 18  |
| 1.8   | Actor Conformance   | .20 |
| 1.8.1 | Constraints on Use Case Actors  | 20  |
| 1.9   | Privacy & Security Guidance   | .24 |
| 1.9.1 | Privacy Considerations  | 24  |
| 1.9.2 | Security Considerations   | 24  |
| 1.10  | CA:FeX Actors and Transactions  | .25 |
| 2     | Use Cases and Definitions   | .26 |
| 2.1   | Use Case Index  | .26 |

| 2.2   | Requirement Priority Definitions                           | 26  |
|-------|--|-----|
| 2.3   | UC-01 Create and Submit Document                           | 28  |
| 2.4   | UC-02 Query and Retrieve Document                          | 33  |
| 3     | Exchanging Documents in FHIR                               | .37 |
| 3.1   | Overview   | 37  |
| 3.2   | FHIR Version   | 38  |
|       | Submit a Document  |     |
|       | Out of Scope   |     |
|       | Use Cases  |     |
|       | CA:FeX Transactions  |     |
|       | HTTP Operations  |     |
| 3.3.5 | Document Submit Patterns: Fundamental                      | 40  |

# 1 CA:FeX Interoperability Specifications

# 1.1 Introduction

Interoperability enables information to flow seamlessly between different solutions and devices. When different parts of the health care system are interoperable with each other, they can "speak the same language." Interoperability improves continuity of care, collaboration between health care providers and patient access to their health information. By breaking down data silos, it also reduces inefficiencies and redundancies within the health care system.

Connection, collaboration and communication have never been more important for the health care system. Increased use of virtual care has highlighted the need for safe and efficient electronic sharing of information across the circle of care. Continuing to improve Canadian health care will necessitate work in interoperability — connected systems are healthier systems.

In support of the provinces and territories, Canada Health Infoway (Infoway) is facilitating a national collaborative effort to advance interoperability. While there are many interoperability-related challenges, this specification addresses standardized sharing of vital patient information for the benefit of health care providers and patients using FHIR based information exchange. This FHIR based information exchange is similar to and accomplishes the same objectives as a Health Information Exchange (HIE).

The Office of the National Coordinator for Health Information Technology (ONC) defines HIE as:

Electronic health information exchange (HIE) allows doctors, nurses, pharmacists, other health care providers and patients to appropriately access and securely share a patient's vital medical information electronically—improving the speed, quality, safety and cost of patient care. While electronic health information exchange cannot replace provider-patient communication, it can greatly improve the completeness of patient's records, (which can have a big effect on care), as past history, current medications and other information is jointly reviewed during visits. Appropriate, timely sharing of vital patient information can better inform decision making at the point of care and allow providers to avoid readmissions, avoid medication errors, improve diagnoses and decrease duplicate testing.

# 1.2 Intended Audience

The intended audience of the CA:FeX Interoperability Specifications (Canadian FHIR Exchange (CA:FeX)), includes but is not limited to:

- Those interested in integrating healthcare information systems and workflows;
- IT departments of healthcare institutions;
- Technical staff of clinical solution vendors;
- · Experts involved in standards development; and
- Software developers.

# 1.3 Purpose

The purpose of this document is to address the following functionality for release 1:

- Address two FHIR HIE use cases;
- Provide a detailed set of requirements (including actors, transactions and references to specific profiles and standards);
- Describe the implementation patterns that enable the exchange of clinical information using CA:FeX; and
- Describe the set of requirements that complement the set of IHE Profiles and and HL7 FHIR<sup>®</sup> Profiles required by the CA:FeX specifications with Canadian specific constraints.

# 1.4 Glossary of Terms and Acronyms

The following terms appear throughout the CA:FeX Specifications:

| Term / Acronym   | Meaning  |  |  |  |  |  |  |
|--|--|--|--|--|--|--|--|
| Author A health care provider who authors and/or curates clinical data.  |  |  |  |  |  |  |  |
| CA:FeX   | The CA:FeX Interoperability Specifications (Canadian FHIR Exchange (CA:FeX)) seeks to<br>promote FHIR RESTful exchange patterns, developed by industry-leading FHIR<br>standards that can be applied on top of an existing non-FHIR infrastructure just as easily<br>as it can be applied on top of FHIR servers.                      |  |  |  |  |  |  |
| Central<br>Infrastructure  | A Central Infrastructure collects health information from participating organizations<br>and stores the information in a centralized place. The Infrastructure also provides<br>access control. Typically, the central infrastructure is under jurisdictional control.   |  |  |  |  |  |  |
| Clinical DataA clinical data repository is built around the HL7 FHIR standard used for sto<br>data.Repositorydata. |  |  |  |  |  |  |  |
| Clinical Solution  | Any combination of health information technology assets and processes that enables clinical data to be communicated, managed and dispositioned between a Producer and a Consumer. Clinical Solutions can be comprised of various Producer and Consumer systems including: EMR, HIS, CIS, PHR, EHR or any combination of these systems. |  |  |  |  |  |  |
| Conformance<br>Testing   | Conformance testing is a formal process of assessment focused on ensuring clinical solutions and systems accurately implement a particular specification (e.g. CA:FeX Specifications) by ensuring there is conformance to the stated parameters that are being claimed in the standard.  |  |  |  |  |  |  |
| Consumer   | A health records system (e.g., EMR, HIS, CIS, PHR, Patient Portal or EHR) that enables access to or receipt of a clinical document (e.g. Patient Summary-CA) by an authorized health care provider or the subject of care/patient.   |  |  |  |  |  |  |
| Document<br>Repository (Local or<br>Central)   | A document repository is a shared storage space for clinical documents that can be hosted locally (i.e., at the document producer) or at the HIE Central Infrastructure and can be accessed by authorized users.   |  |  |  |  |  |  |

| Term / Acronym                            | Meaning  |
|---|--|
| Electronic Health<br>Record (EHR)         | The EHR represents the Clinical Solution that contains a secure and private collection of a patient's health information in a digital format, which is shareable across different health care settings / clinical solutions that are integrated. The EHR facilitates better sharing and interpretation of health information among the health care professionals involved in the care of the patient. For example:   |
|   | <ul> <li>CareConnect is British Columbia's secure, view-only EHR solution. It offers healthcare providers access to an integrated, provincial view of patient-centric information available 24/7 to support the delivery of patient care.</li> <li>HEALTHE NL is the Newfoundland &amp; Labrador provincial EHR. HEALTHE NL will provide more accurate and reliable data to support improved health care delivery, decision-making and policy and create improved accountability, stability and efficiency in the provincial health care system.</li> <li>Netcare is Alberta's name for all the projects related to the provincial EHR - a secure and confidential electronic system of Alberta patients' health information: a single, comprehensive, and integrated patient record.</li> <li>Other clinical systems: In some health authorities, other clinical systems may act as an EHR, holding the patient summary information.</li> </ul> |
| Foundational<br>Interoperability          | Foundational interoperability is the ability of one IT system to send data to another IT system. The receiving IT system does not necessarily need to be able to interpret the exchanged data — it must simply be able to acknowledge receipt of the data payload. This is the most basic tier of interoperability.  |
| НСР                                       | Health Care Provider   |
| Health Information<br>Access Layer (HIAL) | An interface specification for the EHR infostructure that defines service components, service roles, information model and messaging standards required for the exchange of EHR data and execution of interoperability profiles between EHR services.<br>(Source: https://www.infoway-inforoute.ca/en/component/edocman/resources/   |
|   | technical-documents/391-ehrs-blueprint-v2-full ; Page.340)   |
| Health Information<br>Exchange (HIE)      | Electronic health information exchange (HIE) allows doctors, nurses, pharmacists, other<br>health care providers and patients to appropriately access and securely share a<br>patient's vital medical information electronically—improving the speed, quality, safety<br>and cost of patient care.   |
|   | While electronic health information exchange cannot replace provider-patient<br>communication, it can greatly improve the completeness of patients' records, (which<br>can have a big effect on care), as past history, current medications and other<br>information is jointly reviewed during visits.  |
|   | Appropriate, timely sharing of vital patient information can better inform decision making at the point of care and allow providers to avoid readmissions, avoid medication errors, improve diagnoses and decrease duplicate testing.  |
|   | (Source: https://www.healthit.gov/topic/health-it-and-health-information-exchange-basics/what-hie)   |

| Term / Acronym  | Meaning  |  |  |  |  |  |
|---|--|--|--|--|--|--|
| Health Level 7 (HL7)  | Founded in 1987, HL7 is a not-for-profit standards developing organization dedicated to providing a comprehensive framework and related standards for the exchange, integration, sharing, and retrieval of electronic health information that supports clinical practice and the management, delivery and evaluation of health services. (Source: http://www.hl7.org/about/index.cfm?ref=nav)  |  |  |  |  |  |
| HL7 Fast Healthcare<br>Interoperability<br>Resources (FHIR) | Expected to be a next generation standards framework created by HL7. FHIR combines the best features of HL7's Version 2, Version 3 and product lines while leveraging the latest web standards and applying a tight focus on implementability.   |  |  |  |  |  |
|   | (Source: http://www.hl7.org/implement/standards/fhir/)   |  |  |  |  |  |
| Health Records<br>System                                    | A health records system may include an electronic medical records system, a hospital information system, a clinical information system, an electronic health records system or a personal health records system. The term is broadly used to describe system actors that may produce and/or consume a PS-CA. Jurisdictional implementation patterns will determine which systems are used to create, access, consume and manage patient summaries.                             |  |  |  |  |  |
| Integrating the<br>Healthcare<br>Enterprise (IHE)           | IHE is an initiative by healthcare professionals and industry to improve the way<br>computer systems in healthcare share information. IHE promotes the coordinated use<br>of established standards such as DICOM and HL7 to address specific clinical needs in<br>support of optimal patient care. Systems developed in accordance with IHE<br>communicate with one another better, are easier to implement, and enable care<br>providers to use information more effectively. |  |  |  |  |  |
|   | (Source: https://www.ihe.net/)   |  |  |  |  |  |
| IHE Actor   | IHE Actors are responsible for producing, managing and/or acting on information in the context of an IHE Profile (e.g., Primary Care Provider, EMR, EHR, etc.).  |  |  |  |  |  |
|   | (Source: https://wiki.ihe.net/index.php/Actors)  |  |  |  |  |  |
| IHE Profiles  | IHE Profiles describe specific solutions to interoperability problems. Profiles specify how "Actors" use standards to address a specific healthcare use case (e.g., Medication, Allergy Intolerance, etc.).  |  |  |  |  |  |
|   | (Source: https://wiki.ihe.net/index.php/Profiles)  |  |  |  |  |  |
| IHE Transactions  | IHE Transactions are interactions between actors that communicate the required information through standards-based messages (e.g., patient look-up query, send patient summary information, etc.).   |  |  |  |  |  |
|   | (Source: https://wiki.ihe.net/index.php/PCC_TF-1/About)  |  |  |  |  |  |

| Term / Acronym                 | Meaning  |
|--------------------------------|--|
| Producer                       | A health records system (e.g., EMR, HIS, CIS, PHR, or EHR) that creates/produces a clinical document (e.g. Patient Summary-CA) in response to a request from an authorized health care provider, the subject of care or another authorized health records system.  |
| Patient Portal                 | A patient portal is a web-based access point that enables secure patient access to personal health information and other self-serve health IT services. For example, a patient portal can be hosted on an EMR solution.  |
| Semantic<br>Interoperability   | Semantic interoperability is the ability of health IT systems to exchange and interpret information — then actively use the information that has been exchanged. Semantic interoperability is the highest level of interoperability.   |
|                                | "Semantic interoperability takes advantage of both the structuring of the data exchange<br>and the codification of the data including vocabulary so that the receiving information<br>technology systems can interpret the data," stated HIMSS. Achieving semantic<br>interoperability allows providers to exchange clinical information with other caregivers<br>and authorized parties using different EHR systems to improve care quality, safety, and<br>efficiency. This level of interoperability allows healthcare organizations to seamlessly<br>share patient information to reduce duplicative testing, enable better-informed clinical<br>decision-making, and avoid adverse health events. Effective health data exchange can<br>also help to improve care coordination, reduce hospital readmissions, and ultimately<br>save money.<br>While semantic interoperability is the goal, most healthcare organizations are still |
|                                | working to establish foundational and structural interoperability.<br>Hospitals and health care systems can utilize existing health data standards to achieve<br>the lower levels of interoperability and set a solid foundation for future improvements<br>in health data exchange.   |
| Structural<br>Interoperability | Structural interoperability is "the uniform movement of healthcare data from one system to another such that the clinical or operational purpose and meaning of the data is preserved and unaltered," HIMSS states.  |
|                                | To achieve structural interoperability, the recipient system should be able to interpret information at the data field level. This is the intermediate level of interoperability.  |
| Terminology                    | Collection of uniquely identifiable concepts with associated representations, designations, associations and meanings.   |

# 1.5 Preface

The CA:FeX Interoperability Specifications (Canadian FHIR Exchange (CA:FeX)) seek to promote FHIR RESTful exchange patterns, developed by industry-leading FHIR standards that can be applied on top of an existing infrastructure just as easily as it can be applied on top of FHIR servers.

The current version of CA:FeX is focused on the FHIR RESTful exchange of documents, which FHIR offers multiple structures and patterns to achieve. CA:FeX aims to provide clarity to implementers by identifying some of the choices currently available using FHIR, ranging from simple to a higher level of sophistication. As the development of CA:FeX continues, the Interoperability Specifications may evolve into a more formal Integration Profile (similar to existing international profiles reviewed below) that provides more comprehensive guidance on FHIR RESTful exchange patterns than what currently exists today.

It should be noted that the scope of CA:FeX may evolve beyond document-based exchange to explore a more atomic nature of health information exchange in the future. This will depend on the development of a multi-phased CA:FeX roadmap, the evolving needs of the Canadian healthcare market, and emerging trends within the international FHIR health information exchange community.

Upon review of legacy IHE profiles, existing guidance is either based on the enablement of document sharing within non-FHIR infrastructures or through the narrow use of FHIR resources. Given the evolving needs of the Canadian market, these legacy profiles may not be entirely sufficient to enable the FHIR RESTful exchange of documents. Below highlight the two key existing IHE profiles that were contemplated with some of their limitations:

- *Cross-Enterprise Document Sharing (XDS):* This IHE profile is focused on providing a standards-based specification for the sharing of documents which is limited to non-FHIR infrastructures.
- Mobile access to Health Documents (MHD): This IHE profile is designed for the utilization of FHIR syntax to communicate and exchange documents, including, as an option, acting as a proxy to systems that use XDS. MHD leverages FHIR resources (i.e., DocumentReference) as a standard method for clients to find a document. To ensure this IHE profile can be used without regard for how information is stored (i.e., XDS infrastructure, FHIR, or another storage system) the profile applies constraints to the FHIR DocumentReference resource. The current limitation of MHD, however, requires that a document is submitted in FHIR Binary format and does not include the use of a FHIR Bundle (of type Document) to represent documents. Further, MHD entails a multi-step document retrieval process (list/find step followed by the retrieval step) which may not be the single approach implementers will take going forward.

Through a market scan, it was observed that in line with MHD, existing RESTful driven FHIR Implementation Guides that include document exchange (e.g., US Core, IPA, PACIO, IPS, etc.) have begun utilizing a pattern, leveraging the DocumentReference Resource. These Implementation Guides, however, enable querying in a single way and return pointers to document content, wherever it is stored and irrespective of the format (e.g., binary or FHIR-assembled). FHIR Search Parameters and FHIR Operations have been developed to augment the capabilities of this pattern to more easily get back what was requested and enable the offering of documents in the expected format without having to change the underlying data model / document and lifecycle practices.

Within the context of the Canadian market, there is an indication that the level of readiness for exchange patterns outlined by international FHIR Implementation Guides, such as the US Core, may not be appropriate for implementers in the current state. As such, simpler exchange patterns are also a viable alternative. One such alternative is narrowing the focus to the exchange of non-binary documents and utilizing the appropriate FHIR Search Parameters and FHIR Operations based on the Composition Resource to search and retrieve documents.

Given the preliminary findings, both internationally and domestically, CA:FeX outlines the use of FHIR Search and FHIR Operations based on both (i) the DocumentReference Resource and (ii) the Composition Resource. While these methods are surfaced by CA:FeX to drive adoption and feedback, this is still being tested and addressed by the FHIR document exchange community. Furthermore, the current methods explored by this version of CA:FeX do not represent the only FHIR methods available to enable document exchange or, more broadly, health information

exchange as a whole. As international specifications mature and the Canadian market evolves, CA:FeX will dig deeper into the more sophisticated alternatives for health information exchange in order to guide the Canadian market in the same direction.

Due to the continuous development of the market, there will be an opportunity to encompass a broader set of use cases that may deal with the exchange of more atomic information going forward.

In parallel with CA:FeX, Canada Health Infoway is also facilitating a national collaborative effort to develop the pan-Canadian Patient Summary Interoperability Specifications (PS-CA), an implementable, testable specification, based on the IHE International Patient Summary specification and the HL7 IPS Implementation Guide. The PS-CA Reference Architecture will reference the CA:FeX Interoperability Specifications as an optional implementation pattern for submitting, searching and retrieving a Patient Summary document.

## 1.5.1 Context

The pan-Canadian CA:FeX Interoperability Specifications are published to a public space within Canada Health Infoway's InfoScribe and is also available as a downloadable document, here. InfoScribe is a web-based tool developed for jurisdictions and vendors to create, publish, and collaborate on clinical requirements and specifications for interoperability solutions. Teams can document, share, and discuss content, files, ideas, specs, mock-ups, diagrams, and projects. A link to the online published content and the downloadable documentation will be published with each release of CA:FeX.

## 1.5.2 Introduction to IHE

Integrating the Healthcare Enterprise (IHE) is an international initiative to promote the use of standards to achieve interoperability among health information technology (HIT) systems and effective use of electronic health records (EHRs). IHE provides a forum for care providers, HIT experts and other stakeholders in several clinical and operational domains to reach consensus on standards-based solutions to critical interoperability issues.

The primary output of IHE is system implementation guides, called IHE profiles. IHE publishes each profile through a well-defined process of public review and Trial Implementation and gathers profiles that have reached Final Text status into an IHE Technical Framework.

# 1.5.3 How to Read This Document

This document contains the following sections:

| Document Section   | Description  | Target<br>Audience     |
|--|--|------------------------|
| Pan-Canadian<br>CA:FeX<br>Interoperability<br>Specifications | CA:FeX is an implementable, testable specification based on HL7 FHIR<br>Implementation Guides. It defines building blocks to enable FHIR Health<br>Information Exchange (HIE) implementation patterns. CA:FeX building<br>blocks are configurable to address necessary Canadian jurisdictional<br>variances. The CA:FeX Interoperability Specifications, written in line with<br>international best practices, contain the information necessary for an<br>implementer to consume and develop the components necessary for<br>creating, consuming and sharing clinical data and may be applied to<br>existing and new information systems. | Solution<br>Developers |

| Document Section              | Description   | Target<br>Audience                             |
|-------------------------------|---|--|
| Use Cases &<br>Definitions    | The Use Cases & Definitions present the broader context for clinical,<br>business, interoperability and solution development considerations that<br>were discovered during the development of the CA:FeX Interoperability<br>Specifications. This section defines the healthcare problem that CA:FeX<br>addresses and includes healthcare use cases and interoperability<br>requirements in terms that will be traceable to the content in the<br>Reference Architecture, which defines the actors and their interactions in<br>scope for the CA:FeX Interoperability Specifications. | CTOs,<br>CMIOs,<br>CIOs, PTs<br>and<br>Vendors |
| Exchange<br>Documents in FHIR | The Exchange Documents in FHIR section contains methods for<br>implementing the CA:FeX transactions specifically for document<br>exchange using FHIR RESTful APIs. As the content is refined and evolved it<br>will grow into a FHIR implementation guide.  | Solution<br>Developers                         |
| Reference<br>Architecture     | The Reference Architecture contains background information on the<br>abstracted CA:FeX actors and transactions for stakeholders who are not<br>familiar with the IHE methodology. It describes baseline information on<br>the recommended and optional IHE profiles and includes links to the IHE<br>source documentation where stakeholders can get additional details on<br>each CA:FeX actor and transaction.  | CTOs,<br>CMIOs,<br>CIOs, PTs<br>and<br>Vendors |

Within the Pan-Canadian CA:FeX Interoperability Specifications, you can expect the following subsections:

- Introduction & Preface: Contains an introduction to the pan-Canadian CA:FeX Interoperability Specifications. This section contains a summary of the context, document purpose and scope, as well as other content to help orient the first-time reader to the topic of these specifications and how they relate to other specifications in the digital health ecosystem in Canada.
- Use Case Overview: Describes the Use Cases, including design constraints and assumptions and the flows of information that will be specified in the CA:FeX Interoperability Specifications. This section also references scenarios that describe how the specified flows may be used in the Canadian context.
- **Core Interoperability Specification Requirements:** Establishes the Core Interoperability Requirements for the CA:FeX Interoperability Specifications with respect to a FHIR Health Information Exchange (HIE) implementation pattern. This section also provides mapping of use case actors to the technical actors of the CA:FeX Interoperability Specifications and the services they are supporting, which are aligned with the flow captured in the sequence diagrams included in the Reference Architecture section.
- **CA:FeX Actor Conformance:** Establishes the Actor Conformance Requirements for the CA:FeX Interoperability Specifications.
- **Privacy & Security Guidance:** Provides a link to a Digital Health Privacy Toolkit that is under development and describes key Security considerations for the CA:FeX Interoperability Specifications.
- **CA:FeX Actors and Transactions:** Illustrates the abstracted actors and transactions in scope for the CA:FeX Interoperability Specifications.

## 1.5.4 Document Conventions

The pan-Canadian CA:FeX Interoperability Specifications will be numbered according to this format:

- Name + Version + Stage, where name refers to the name of the document, version refers to the versioning history of the document and stage refers to its stage in implementation such as "Trial Implementation" or "TI".
- Key documents will evolve during review cycles from version 0.x to v1.0.

### 1.5.5 Requirements Language

The following conventions are used to specify requirement levels for the business requirements of the pan-Canadian CA:FeX Interoperability Specifications:

- Shall: used to indicate a required requirement.
- **Should:** used to indicate that a requirement is **recommended** and should be considered as best practice for implementation, but not required (i.e., it is optional) for implementation.
- May: used to indicate that a requirement is permittable / optional, but not required for implementation.
- Shall not: used to indicate that an element or action is prohibited.

Additional information on the CA:FeX business requirements can be found in the Use Cases and Definitions section.

## 1.5.6 Methodology

The pan-Canadian CA:FeX Interoperability Specifications document has been developed based on international research and stakeholder consultations with HIE Subject Matter Advisors, where this was socialized and validated with the leading jurisdictions and vendors through Coordinating Table Meetings, Executive Table Meetings, stakeholder workshops and 1-on-1 meetings to further refine the specifications.

## 1.5.7 Introduction to a Use-Case Driven Approach

The following use case-driven approach was utilized in the development of the pan-Canadian CA:FeX Interoperability Specifications:

- **Baseline:** Develop foundational Use Cases, Use Case Scenarios and Business Requirements for FHIR Health Information Exchange (HIE).
- **Collaborate:** Collaborate with jurisdictions, clinical SMEs, technical SMEs, vendors, participating organizations to develop and refine detailed artefacts.
- Review: Review and provide feedback into artefacts through engagement workshops and input gathering.
- **Publish:** Publish artefacts for broader stakeholder consultation.
- **Recommend:** Recommend draft artefacts for approval.
- Iterate: Continue to refine as per testing and priorities.

# 1.5.8 Release Cycle

The CA:FeX Interoperability Specifications' release cycle will include a multi-stage review and feedback process, as documented here.

# 1.6 CA:FeX Use Case Overview

### 1.6.1 Use Case Overview

This section describes the two Use Cases for the FHIR Health Information Exchange (HIE) Implementation Pattern, including all design constraints and assumptions as well as the flows of information that will be specified in this pan-Canadian CA:FeX Interoperability Specifications v1 Trial Implementation document. This section also introduces the scenarios that describe how the specified workflows may be used in the Canadian eHealth context.

## 1.6.2 In-Scope

The following Use Cases are in scope for Release 1 of the pan-Canadian CA:FeX Interoperability Specifications v1 Trial Implementation:

- UC-01 Create and Submit Document
- UC-02 Query and Retrieve Document

### 1.6.3 Use Case Actors and Services

The Use Case Actors and the Services that are used by this specification are described below. Additional information can be found in the Core Interoperability Specifications Requirements section.

| Description / Definition  |  |  |  |
|---|--|--|--|
| A health records system (e.g., EMR, HIS, CIS, PHR, or EHR) that creates/produces clinical data in response to a request from an authorized health care provider, the subject of care or another authorized health records system.   |  |  |  |
| A health records system (e.g., EMR, HIS, CIS, PHR, Patient Portal or EHR) that<br>enables access to or receipt of clinical data by an authorized health care provide<br>or the subject of care/patient.   |  |  |  |
| A Clinical Data Repository is a shared storage space for clinical documents that can be hosted locally (e.g., at the data producer) or at the Central Infrastructure and can be accessed by authorized users.   |  |  |  |
| A Central Infrastructure collects health information from participating<br>organizations and stores the information in a centralized place. The<br>Infrastructure also provides access control. Typically, the Central Infrastructure is<br>under jurisdictional control. |  |  |  |
|   |  |  |  |

#### Use Case Actors and Descriptions

| Actor Name                                  | UC-01 | UC-02 |
|---|-------|-------|
| Producer                                    | х     |       |
| Consumer                                    |       | x     |
| Clinical Data Repository (Local or Central) | x     | x     |
| Central Infrastructure                      | x     | x     |

## 1.6.4 Design Constraints & Assumptions

The following design constraints and assumptions exist for the pan-Canadian CA:FeX Interoperability Specifications:

- All Use Case Actors/Users are logged in to the system. The Use Case Actors/Users are authenticated and appropriately authorized for all data exchange transactions.
  - Our recommendation is that the Use Case Actors/Users obtain a valid access token from the Authorization Server that is used within each transaction and is based on the IUA IHE Profile.
  - Vendors or jurisdictions may decide not to implement optional IHE profiles such as IUA, ATNA and CT, however it is highly recommended that areas pertaining to authentication, auditing and security are being addressed using solutions that currently exist in their respective enterprise architecture.
- Local data sources are in scope for Release 1.
  - There may be exceptions to the data source of some of the clinical data across jurisdictions in Canada. For example, for some jurisdictions, the immunization data will be pulled from the provincial immunization repository.

# 1.7 Core Interoperability Specification Requirements

# 1.7.1 Actor Mapping to Interoperability Specification

The Use Case Actors and the Services they support are described at a functional level in the Use Cases and Definitions section of the CA:FeX Interoperability Specifications. Services may be Required or Optional. The Use Case Actor, Service(s) and optionality are conveyed in the first three columns of Tables 1 and 2 in the section below. The second part of the table (columns 4-7) provides the mapping for the Use Case Actor to the detailed specifications (such as Technical Actors and Optionality) that systems shall implement to exchange healthcare information in the context of these use cases. The purpose of the tables below is to map the use case actors to the technical actors and the services they are supporting. These tables are aligned with the flow captured in the sequence diagrams which are included in the Reference Architecture section.

For a selected Use Case Actor (a single row in the table), the system shall implement all of the requirements (some optionality when allowed) listed in the second part of the table (columns 4-7). This includes the referenced healthcare profiles, the standards specified and terminology standards. For Technical Actors, which map to CA:FeX or an IHE Profile (*CA:FeX, PDQm, PMIR, etc.*), the last column provides the reference location of the specification. Links for these referenced specifications have been included in the tables below. Additionally, the below table does not showcase all of the possible combinations of IHE profiles and transactions that can be used for a particular implementation pattern. For example, 'Identify Patient' service can use PIXm in place of PDQm if the preferred implementation pattern is PIXm/PMIR.

#### Versioning

This is an evolving specification; the release cycle assumes some degree of change will happen across versions. We've established a versioning protocol and will be clearly communicating the version of the artefacts that are employed by the CA:FeX Interoperability Specifications and will ensure testing aligns to it. There will be a process in place to monitor changes in the current versions of the IHE profiles which will be incorporated in future versions of the CA:FeX Interoperability Specifications based on our interoperability roadmap.

#### **Published Versions**

The following describes the published versions in scope for the required and optional IHE Profiles that have been referenced in this specification:

- IUA: Revision 2.1 Trial Implementation
- PDQm: v2.3.0: Trial Implementation based on FHIR R4
- PMIR: Revision 1.3 Trial Implementation

#### <u>Legend</u>

R = Required

O = Optional

# 1.7.2 Table 1 Interoperability Conformance Requirements for Use Case 1: Create and Submit Document

| USE CASE 1: Create and Submit<br>Document |   |     | MAPPING TO SECTIONS FROM THIS AND REFERENCED<br>INTEROPERABILITY SPECIFICATIONS |     |  |  |

# 1.8 Actor Conformance

A system conforming to the CA:FeX Interoperability Specifications shall claim conformance at the level of a Use Case Actor (first columns of Table 1 and Table 2 of section Core Interoperability Specification Requirements). A system may claim conformance to one or more Use Case Actors among:

- Producer
- Consumer
- Clinical Data Repository (Local or Central)
- Central Infrastructure

Producer and Consumer use case actor roles will primarily be taken up by EMR clinical solution vendors. Clinical Data Repository and Central Infrastructure use case actor roles can be taken up either by EMR clinical solution vendors or jurisdictions depending on the implementation approach that the jurisdiction decides to adopt. Similarly, the Consumer can be a Patient Portal, in which case the use case actor can be taken up either by a vendor or jurisdiction depending on the approach and policies defined regarding patient / subject of care access to their personal health information (PHI).

In order to implement a system that fully supports the CA:FeX Interoperability Specifications v1 Trial Implementation, the system shall be able to demonstrate that it conforms to every required actor and transaction for which it is claiming conformance.

# 1.8.1 Constraints on Use Case Actors

The section below captures some of the design constraints on use case actors when developing functionality to support the services mapped to them.

**Note**: The scope of this section is limited to the constraints that are applicable to actors and transactions defined for CA:FeX Interoperability Specifications (See section CA:FeX Actors and Transactions). The two key services supported by CA:FeX are:

- Save Document to Clinical Data Repository
- Retrieve Document from Clinical Data Repository

The following section provides key design constraints for implementation of these two required services using RESTful APIs based on CA:FeX and FHIR standards. To support these two services, the following three RESTful transactions have been defined:

| Service Supported                                  | FHIR RESTful Transactions   |
|--|-----------------------------|
| Save Document to Clinical Data Repository          | 1. Submit Data [CA:FeX-1]   |
| Retrieve Document from Clinical Data<br>Repository | 2. Search Data [CA:FeX-2]   |
|  | 3. Retrieve Data [CA:FeX-3] |

#### Save Document to Clinical Data Repository

The Producer and Clinical Data Repository Use Case Actors are required to implement the *Save Document to Clinical Data Repository* service.

These actors shall use the FHIR transaction **Submit Data [CA:FeX-1]** of CA:FeX that executes a *Submit Data request* from a Data Source to a Data Recipient.

#### Submit Data [CA:FeX-1]

This message involves a request by a Data Source to transfer a FHIR document to a Data Recipient. The request is received by a Data Recipient which stores the received FHIR documents and returns an HTTP response code.

#### Trigger Events

This method is invoked when the Data Source needs to submit one or more FHIR documents to a Data Recipient (Clinical Data Repository).

#### Message Semantics

This message uses the HTTP POST method on the target Submit Data endpoint to convey the metadata and the document(s) as a FHIR transaction. The Data Source shall initiate a FHIR "transaction" using a "create" action by sending an HTTP POST request method composed of a FHIR Resource. The media type of the HTTP body shall support application/fhir+json and should support application/fhir+xml. Additional information on this FHIR implementation pattern is provided in the Submit a Document section under Exchanging Documents in FHIR.

#### **Expected** Actions

The Data Recipient shall accept media types application/fhir+json and application/fhir+xml. On receipt of the submission, the Data Recipient shall validate the resources and respond with one of the HTTP response codes and an OperationOutcome, if applicable. Additional information on handling responses is provided in Response Handling section under Exchanging Documents in FHIR.

#### Retrieve Document from Clinical Data Repository

The Consumer and Clinical Data Repository (Central) Use Case Actors are required to implement the *Retrieve Document from Clinical Data Repository* service.

These actors shall use the following transactions to find metadata and retrieval of identified clinical document:

- Search Data [CA:FeX-2]
- Retrieve Data [CA:FeX-3]

#### Search Data [CA:FeX-2]

This message involves a query request by a Data Consumer to find FHIR documents using parameterized queries. The request is received by a Data Recipient which returns a Bundle containing the matching search parameters.

The Data Consumer may use HTTP GET or HTTP POST based searches. The Data Responder shall support both GET and POST based searches.

#### Trigger Events

When a Data Consumer needs to discover a list of FHIR Bundle Resources or retrieval of documents that are anticipated to be a mix of FHIR-assembled (Composition) and FHIR-enabled (Binary) documents.

#### **Message Semantics**

The Data Consumer executes an HTTP search request against the Data Responder endpoint (FHIR Repository).

The Data Consumer may use HTTP GET or HTTP POST based searches. The Data Responder shall support both GET and POST based searches.

#### GET [base]/[resourcetype]?name=value&...

#### POST [base]/[type]/\_search{?[parameters]{&\_format=[mime-type]}}

#### Query Search Parameters

The following search parameters are used generically to support document retrieval.

Additional search parameters that are specific to the requirements for a specific use case or IGuide (e.g., PS-CA) may be further defined by those implementations.

| Query Search Parameters | Applied to  | Description  |
|-------------------------|---|--|
| composition             | bundle.composition  | This parameter, of type reference, specifies the first<br>resource in the bundle, if the bundle type is<br>"document" - this is a composition, and this<br>parameter provides access to search its contents<br>using chaining. See FHIR Chaining Parameters<br>search methodology. |
| timestamp               | bundle.timestamp  | This parameter, of type date, specifies the timestamp when the FHIR bundle was created. See FHIR http://hl7.org/fhir/R4/search.html#date for use of the date search type.  |
| patient.identifier      | bundle.composition.patie<br>nt.identifier<br>documentReference.patie<br>nt.identifier | This parameter, of type token, specifies an identifier<br>associated with the patient to which the document<br>is assigned. This use of patient.identifier follows the<br>FHIR Chaining Parameters search methodology.   |
| type                    | bundle.composition.type<br>documentReference.type                                     | This parameter, of type token, specifies the kind of<br>document (LOINC if possible). The use of<br>bundle.composition.type follows the FHIR Chaining<br>Parameters search methodology, whereas type can<br>be applied directly in documentReference<br>searches.                  |
| author                  | bundle.composition.auth<br>or<br>documentReference.auth<br>or                         | This parameter, of type reference, specifies who<br>and/or what authored the document. The use of<br>bundle.composition.author follows the FHIR<br>Chaining Parameters search methodology, whereas<br>author can be applied directly in<br>documentReference searches.             |
| date                    | bundle.composition.date<br>documentReference.date                                     | This parameter, of type date, specifies when this<br>document reference was created. The use of<br>bundle.composition.date follows the FHIR Chaining<br>Parameters search methodology, whereas date can<br>be applied directly in documentReference<br>searches.                   |

Additional information on this FHIR implementation pattern including Document Search Pattern options is provided in the Search for a Document section under Exchanging Documents in FHIR.

#### **Expected Actions**

The Data Responder shall process the query and return a search result matching the search criteria included in the request. The FHIR standard provides encodings for responses as either XML or JSON.

Additional information on handling responses is provided in the Response Handling section under Exchanging Documents in FHIR.

#### Security Considerations

Data Responder SHALL reject any unauthorized requests by returning an HTTP 401 unauthorized response code. This transaction should not return information that the Data Consumer is not authorized to access. Where authorization here is inclusive of system, app, and user according to local policy, patient consents, and security layering. However, the transaction may return search bundle that have Reference elements that the Data Consumer may not have access to. This is to say that the authorization need only be to the content returned in the Bundle. There may be references (URLs) for which the content is not authorized. This is considered proper as the Data Consumer would need to retrieve the content pointed to by those references, and at that time the proper authorization decision would be made on that context and content. In this way it is possible for a Data Consumer to get Resources that are pointing at data that the Data Consumer is not authorized to retrieve. Thus, the URLs used must be carefully crafted so as to not expose sensitive data in the URL value.

#### Retrieve Data [CA:FeX-3]

This message involves a request by a Data Consumer for retrieving known documents using the document's resource id from a Clinical Data Repository. The request is received by a Data Responder which returns the requested FHIR document(s) or returns an HTTP response code.

This message uses the HTTP GET request to retrieve the identified FHIR document(s) from the central Clinical Data Repository.

#### Trigger Events

This method is invoked when the Data Consumer needs to retrieve FHIR document(s).

#### **Message Semantics**

The Data Consumer sends an HTTP GET request to the server based on a known resource id from the Data Responder. This operation will return a Bundle that was previously identified in a search/or prior retrieval or an embedded attachment in DocumentReference or a Binary resource.

#### GET [base]/[resourcetype]?name=value&...

Additional information on this FHIR implementation pattern including Document Search Pattern options is provided in the Retrieve a Document section under Exchanging Documents in FHIR.

#### **Expected Actions**

The Data Responder shall process the GET request and respond with FHIR Document (s) matching the specified identifier included in the request. When the requested document is returned, the Data Responder shall respond with an HTTP Status Code 200. The HTTP message-body shall be the content of the requested document.

Additional information on handling responses is provided in the Response Handling section under Exchanging Documents in FHIR.

#### Security Considerations

Data Responder SHALL reject any unauthorized requests by returning an HTTP 401 unauthorized response code. This transaction should not return information that the Data Consumer is not authorized to access.

# 1.9 Privacy & Security Guidance

# 1.9.1 Privacy Considerations

(i) A Digital Health Privacy Toolkit is under development and it will be a companion guide for the CA:FeX Interoperability Specifications. This Toolkit will be available and referenced here as part of the CA:FeX v1 Trial Implementation release.

# 1.9.2 Security Considerations

(i) Fast Healthcare Interoperability Resources (FHIR) is not a security protocol, nor does it define any security related functionality. However, FHIR does define exchange protocols and content models that need to be used with various security protocols defined elsewhere.

FHIR transactions defined as part of the CA:FeX implementation pattern often make use of patient-specific information which could be exploited by malicious actors resulting in exposure of patient data. For this reason, all FHIR transactions must be secured appropriately with access to limited authorized individuals, data protected in transit, and appropriate audit measures taken.

Implementers SHOULD be aware of security considerations associated with FHIR transactions (http://hl7.org/fhir/R4/security.html), particularly those related to:

- Communications
- Authentication
- Authorization/Access Control
- Audit Logging
- Digital Signatures
- Security Labels
- Narrative

Additionally, many FHIR transactions using HTTP REST will include query parameters that would be identifiers, quasi-identifiers, or sensitive health topics. For example, it is common for patient identifier to be a query parameter. With this URL pattern, the query parameters are typically visible in the server audit log or browser history. The risk from this visibility should be mitigated in system or operational design, by protecting the logs as sensitive data, or by designing other measures into the system to prevent inappropriate exposure.

# 1.10 CA:FeX Actors and Transactions

The following diagram illustrates the actors and transactions in scope for the CA:FeX Interoperability Specification.

|                   | CA:FeX*<br>Data<br>Isumer      | CA:FeX*<br>Data<br>Recipient                  | CA:FeX*<br>Data<br>Responder | CA:FeX |
|-------------------|--------------------------------|---|------------------------------|--------|
| CA:FeX* Submit Da | CA:FeX* Search Data [CA:FeX-2] | Outcome)<br>Return Data Bundle<br>Return Data |                              |        |

There are three primary transactions for the CA:FeX Interoperability Specification, along with additional subtransactions listed below for specific circumstances. Please refer to the Exchanging Documents in FHIR section for more details.

| Transaction ID | Description   |
|----------------|---|
| CA:FeX-1       | Submit Data   |
| CA:FeX-2       | CA:FeX-2A: Search Against FHIR Assembled Documents Repository         |
|                | CA:FeX-2B: Search Against Hybrid Documents Repository                 |
| CA:FeX-3       | CA:FeX-3A: Retrieve Document From FHIR Assembled Documents Repository |
|                | CA:FeX-3B: Retrieve Document from Hybrid Documents Repository         |

# 2 Use Cases and Definitions

The purpose is to describe the use cases and workflow scenarios for sharing clinical documents across solutions. Each jurisdiction may have implementation variances within the use cases. Therefore, these use cases do not represent required implementation choices, nor are they representative of all possible implementation choices. These uses cases are to be considered as examples. The use cases provide high-level interactions between a Health Care Provider or Patient using a Clinical Solution (e.g., EMR, Patient Portal, etc.) and the HIE. Use cases provide the business description or "conversation" between the system(s) and its user(s), known as Participants. Participants can be people (e.g., health care providers, patients, etc.) using a Clinical Solution (e.g., EMR, Patient Portal) or systems (e.g., HIE, etc.). Please note that detailed interactions are defined in the Reference Architecture section of this document.

Each use case will include:

- use case scenario,
- examples of use case triggers, pre- and post-conditions,
- who the participants are (i.e., people and systems),
- a use case diagram to provide a visual representation of the interactions between participants,
- use case steps corresponding to the diagram and potential alternate flows, and
- requirements.

# 2.1 Use Case Index

This section includes a proposed list of use cases which were identified as being priority use cases in the pan-Canadian environmental scan. Additional use cases will be defined in future releases.

#### The scope for this release of the CA:FeX Specifications has been defined to include use cases UC-01 and UC-02.

The list below includes the use cases a Use Case ID, name and description of the use case.

| Use Case<br>ID | Use Case Name                  | Use Case Description   |
|----------------|--------------------------------|--|
| UC-01          | Create and Submit<br>Document  | A Health Care Provider, in any care setting, adds Patient clinical information for use at point of care, which is made available to other authorized HCPs.   |
| UC-02          | Query and Retrieve<br>Document | Query and retrieval of clinical documentation performed by a Health<br>Care Provider for use at the point of care or by the Patient themselves<br>to obtain a copy of their own personal health information. |

# 2.2 Requirement Priority Definitions

| Priority | Definition  |
|----------|---|
| SHALL    | • used to indicate a <b>required</b> requirement. |

| Priority | Definition   |
|----------|--|
| SHOULD   | <ul> <li>used to indicate that a requirement is <b>recommended</b> and <b>should</b> be<br/>considered as best practice for implementation, but not required (i.e., it<br/>is optional) for implementation.</li> </ul> |

# 2.3 UC-01 Create and Submit Document

A Health Care Provider, in any care setting, adds Patient clinical information for use at point of care, which is made available to other authorized HCPs.

#### Scenario

A patient schedules a visit with their regular health care provider, within their Medical Home, with symptoms including dizziness and an earache. The patient mentions that since they last visited, another clinic noted that they have high blood pressure (hypertension) which is being monitored at home for now. The patient also mentions a suspected penicillin allergy. The health care provider determines that the patient has an external ear infection (otitis externa) and prescribes antibiotics. The health care provider creates a clinical note in their EMR, which may trigger automatic updates, such as updates to the prescription information. The health care provider decides to submit this new information to the network (i.e., Clinical Data Repository) so that it is available for other health care providers who may be providing care for this patient.

This section describes example triggers, pre-conditions & post-conditions related to uploading new clinical information to the Clinical Data Repository. It is not inclusive of all potential workflow scenarios which may be implemented within Canadian jurisdictions.

Triggers

- Health Care Provider provides care to a patient and adds clinical information to the Patient's record.
- Health Care Provider receives additional information for a patient that they wish to share with other HCPs. For example, HCP receives test results for a Patient and adds the clinical information to the Patient's problem list.

Pre-conditions

- Clinical documentation shall uniquely identify the Patient so that it can be uploaded to the Clinical Data Repository and available to other HCPs (e.g., uniquely identified by a Client Registry ID)
- In jurisdictions where explicit consent is required to share Patient clinical information:
  - Patient provides, or has previously provided, consent to share their data to the Clinical Data Repository.

#### Post-conditions

- New Patient clinical information recorded/registered in the Clinical Data Repository.
- Authorized health care providers have access to view the Patient's clinical information or may receive a notification that new clinical information about the patient is available.

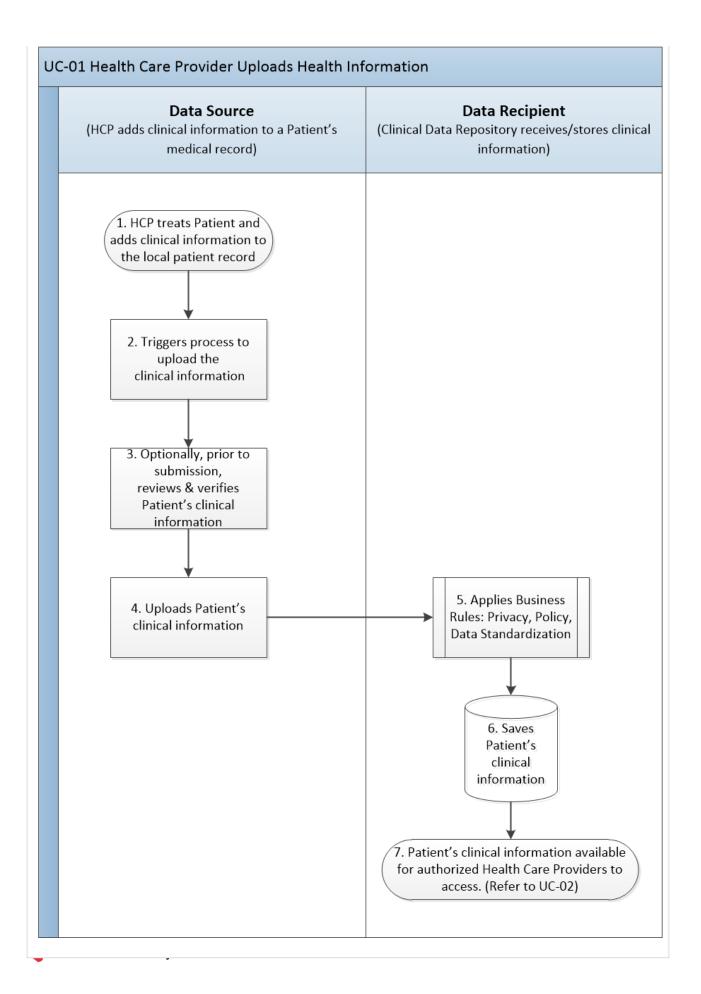

#### Use Case Participants & Diagram

The participants involved in this use case are:

- Data Source (Health Care Provider adding/updating patient clinical information via their local Clinical Solution (e.g., EMR))
- Data Recipient (Clinical Data Repository receiving/storing the Patient's clinical information)

This use case diagram represents the participants and their role in the use case with a high-level view of the flow of information.

#### **Use Case - Primary Flow**

The following provides a textual description corresponding to the use case diagram.

- 1. Health Care Provider treats Patient and adds clinical information to the Patient's health record in their local Clinical Solution (e.g., EMR, HIS).
- 2. Health Care Provider decides to share the new clinical information collected and triggers the process to upload the information to the Clinical Data Repository.
- 3. Health Care Provider, optionally, reviews and validates the Patient's clinical information prior to sharing/ uploading it to the Clinical Data Repository.
- 4. Health Care Provider sends / uploads the Patient's clinical information to the Clinical Data Repository.
- 5. Clinical Data Repository applies business rules (e.g. data standardization, privacy, policy, etc.). For example:
  - a. Validation of Patient Summary data (e.g. Provider identified and eligible to submit clinical information, Patient identified, etc.)
  - b. Checks for existing clinical information for same patient/same provider apply replacement / archiving rules
- 6. Clinical Data Repository saves the Patient's clinical information.
  - a. Clinical Data Repository responds to the submitting system to indicate that the submission was accepted (i.e., recorded/registered) or it was a bad request.
- 7. Patient's clinical information is available for access by authorized Health Care Providers. (Refer to UC-02 Query and Retrieve Document)

#### **Use Case - Alternate Flow**

The following list provides possible alternate flows that may occur within this use case.

- Step 3: Health Care Provider has the option to bypass an additional review of the clinical information, allowing the Clinical Solution to automatically share/upload the Clinical Information to the Clinical Data Repository.
- Step 3: Health Care Provider, upon review of the clinical information, chooses to make changes within the local Patient's health record prior to uploading it to the Clinical Data Repository.
- Step 4: Health Care Provider, after submitting the Patient's clinical information, identifies that there is incorrect or missing information. The HCP will have the option to modify and upload the corrected clinical information to the Clinical Data Repository.
- Step 4: Health Care Provider, after submitting the Patient's clinical information, identifies that incorrect information has been uploaded (e.g., information is for the wrong patient). The HCP will have the option to retract / delete the information from the Clinical Data Repository.

#### Use Case - Requirements

The following is a list of key requirements that will be addressed as part of this use case.

| # | Category | Requirement Description  |
|---|----------|--|
| 1 | Write    | FHIR API SHALL be capable of accepting write operations to<br>allow creation of new clinical document in the central Clinical<br>Data Repository   |
| 2 | Response | FHIR API SHALL be capable of returning a response that a new clinical information has been successfully recorded/registered in the central Clinical Data Repository                              |
| 3 | Response | FHIR API SHALL be capable of returning a response that a<br>Patient clinical information could not be recorded/registered<br>in the central Clinical Data Repository (HTTP 400 - Bad<br>Request) |

# 2.4 UC-02 Query and Retrieve Document

Query and retrieval of clinical documentation performed by a Health Care Provider for use at the point of care or by the Patient themselves to obtain a copy of their own personal health information.

#### **Example Scenarios:**

# 1) A Health Care Provider, in any care setting, queries and retrieves a clinical document for use at the point of care

A patient schedules a visit with a health care provider, outside of their Medical Home, with symptoms including dizziness and an earache. The patient mentions that they have a regular health care provider, within their Medical Home, and experiences high blood pressure (hypertension) which is being monitored at home for now. The health care provider collects information from the patient and, using their Clinical Solution (e.g., EMR), searches for clinical information (e.g., searches the network to locate clinical documentation created and shared by another Health Care Provider). Upon finding a clinical document(s) for their patient, the health care provider views and uses the information in support of providing care for this patient.

# 2) A Patient or Subject of Care accesses/views and can obtain a copy of their own personal health information.

A patient, or their designated caregiver, would like to access their personal health information (PHI) to stay up to date with their medical health information, empowering them to play an active role in their own care.

# This section describes example triggers, pre-conditions & post-conditions related to the query and retrieval of clinical document(s) from the Clinical Data Repository. It is not inclusive of all potential workflow scenarios which may be implemented within Canadian jurisdictions.

#### Triggers

Scenario 1:

- Patient visits Health Care Provider for care.
- Where applicable, HCP received a notification that new clinical information is available for the Patient to which they have subscribed to receive notifications.

#### Scenario 2:

- Patient, or their designated caregiver, chooses to view personal health information to stay informed of their medical information.
- Patient wants to obtain a copy of their personal health information to have on their person while travelling.
- Patient wants to obtain a copy of their personal health information to share with another care provider.

#### Pre-conditions

Scenario 1:

- Health Care Provider is logged in to their Clinical Solution (e.g., EMR).
- Health Care Provider's Clinical Solution is connected / part of the Clinical Data Repository network.

#### Scenario 2:

- In jurisdictions where a patient may have applied consent directives to their clinical information, HCP complies with local/jurisdictional privacy policies.
- A jurisdictional clinical system with patient access is available.
- If applicable, patient has designated and authorized a designated caregiver to access their personal health record on their behalf.

#### Post-conditions

#### Scenario 1:

• Health Care Provider views and uses the clinical document(s) in support of Patient care.

#### Scenario 2:

- Patient, or their designated caregiver, accessed/viewed, and optionally printed a copy of, their personal health information.
- Patient, or their designated caregiver, presents their personal health information to another health care provider to support continuity of care.

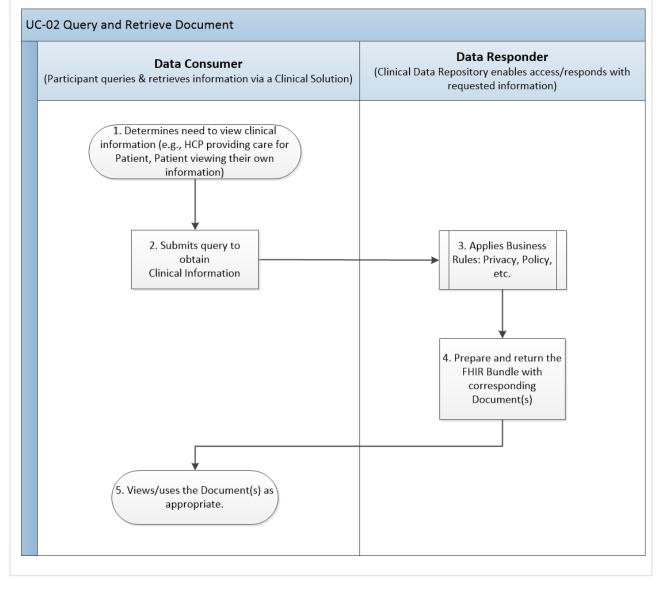

#### Use Case Participants & Diagram

The participants involved in this use case are:

- Data Consumer (Clinical Solution, e.g., EMR used by the Health Care Provider to request & retrieve access to clinical document(s) from the Clinical Data Repository; Patient Portal used by the Patient / Subject of Care to request & retrieve access to their clinical document(s) from the Clinical Data Repository)
- Data Responder (Health Records System acting as the Clinical Data Repository enabling access and responding with the requested clinical document(s))

This use case diagram represents the participants and their role in the use case with a high-level view of the flow of information.

#### **Use Case - Primary Flow**

The following provides a textual description corresponding to the use case diagram.

- 1. Participant (i.e., Health Care Provider or Patient / Subject of Care) determines need to view clinical information.
- 2. Participant requests access (i.e., queries) for clinical information via the clinical solution.
- 3. Clinical Data Repository applies applicable business/policy rules (e.g. validates requestors credentials).
- 4. Clinical Data Repository prepares and returns the FHIR bundle with corresponding clinical document(s).
- 5. Participant views/uses the clinical document(s) in support of care for the Patient or themselves.

#### **Use Case - Alternate Flow**

The following list provides possible alternate flows that may occur within this use case.

• Step 3: Patient Consent Services are not currently supported in the CA:FeX specifications. However, Patient consent is considered as a roadmap item and would be represented in a separate use case at that time where a Patient has identified consent directives requiring the Health Care Provider to address prior to accessing the Patient's clinical information. It is recognized that some jurisdictions may have existing Patient Consent Services implemented and should be considered when implementing with that jurisdiction.

#### **Use Case - Requirements**

The following is a list of key requirements that will be addressed as part of this use case.

| # | Category | Requirement Description  |
|---|----------|--|
| 1 | Query    | FHIR API SHALL be capable of executing searches based on a Patient Identifier  |
| 2 | Query    | FHIR API SHALL be capable of executing searches based on a specified date range  |
| 3 | Query    | FHIR API SHOULD be capable of executing searches based on specific Document Type that the health care provider is interested in retrieving   |
| 4 | Query    | FHIR API SHALL be capable of accepting requests originating<br>from a patient portal or any other system that allows a patient<br>to initiate a request to access their personal health information<br>(PHI) |
| 5 | Response | FHIR API SHALL be capable of responding to requests for<br>retrieval of clinical information for requests initiated by patient<br>to access their PHI  |

# 3 Exchanging Documents in FHIR

(i) The transactions presented below represent an initial solution to the identified use cases and are expected to evolve, particularly as we hear from the implementer community and use cases are refined and added. We encourage the community to provide feedback on these emerging specifications.

# 3.1 Overview

HL7 characterizes a document by the following properties:

- Persistence Documents are persistent over time. The content of the document does not change from one moment to another. A document represents information stored at a single instance in time.
- Wholeness A document is a whole unit of information. Parts of the document may be created or edited separately, or may also be authenticated or legally authenticated, but the entire document is still to be treated as a whole unit.
- Stewardship A document is maintained over its lifetime by a custodian, either an organization or a person entrusted with its care.
- Context A clinical document establishes the default context for its contents.
- Potential for authentication A clinical document is an assemblage of information that is intended to be legally authenticated.

This specification defines a document as a record (written, printed or electronic) that compiles information about a patient's care for a particular purpose or workflow. Documents are distinct from the medical data that may be included in the document as they provide an additional layer of context and metadata around how and why the pieces of medical data were compiled.

Examples of documents include discharge summaries, history & physical notes, medical imaging reports, patient summaries, and more.

## Scope

This specification is starting with the exchange of documents (and their respective resources) in FHIR. As the CA:FeX Interoperability Specifications evolve, it will be expanded to tackle the exchange of individual FHIR resources that can be exchanged independent of a document workflow (e.g., retrieval of last 3 years of dispensed medications).

While HL7 FHIR defines a document format for documents that are authored and assembled in FHIR (See FHIR Composition Resource), this specification also acknowledges that FHIR can be used to exchange documents that are constructed in other formats (e.g., FHIR Binary).

The PS-CA (pan-Canadian Patient Summary) is being used as the first type of document to identify possible transaction patterns and requirements that could be extrapolated to other types of documents.

The CA:FeX Interoperability Specifications will provide detailed information for the following transactions.

| Transaction ID | Description |
|----------------|-------------|
| CA:FeX-1       | Submit Data |

| Transaction ID | Description   |
|----------------|---|
| CA:FeX-2       | CA:FeX-2A: Search Against FHIR Assembled Documents Repository         |
|                | CA:FeX-2B: Search Against Hybrid Documents Repository                 |
| CA:FeX-3       | CA:FeX-3A: Retrieve Document From FHIR Assembled Documents Repository |
|                | CA:FeX-3B: Retrieve Document from Hybrid Documents Repository         |

# 3.2 FHIR Version

FHIR content in this specification is based on on FHIR Release 4 (R4).

# 3.3 Submit a Document

## Scope

This capability is currently scoped to the ability to submit new FHIR Documents.

While there are a variety of ways documents can be modeled and exchanged in FHIR, the initial release of this specification is focused on the submission patterns expected to be used by early implementers of the PS-CA (pan-Canadian Patient Summary). Patient Summaries are a relatively new document type (e.g., legacy implementations not expected) and have been modeled as FHIR Documents.

FHIR Documents are Bundle resources with the type of "document" and which contain a Composition resource as the first entry, and key referenced resources as additional Bundle entries. For more on FHIR Documents, see Documents.

# 3.3.1 Out of Scope

As this specification evolves, and new document types and architectures are included, this scope will also evolve to supply guidance for those business cases.

Global, pan-Canadian, and jurisdictional practices for document lifecycle management of patient summaries are still in development. For this reason, the management, verification, replacement and deprecation of documents, are out of scope of the guidance included in this release.

#### (i) Info

Implementers expecting to support use cases involving multiple patient summaries over time are still expected to familiarize themselves with the boundaries the FHIR standard applies to document immutability. Once assembled into a document bundle, the document is immutable - its content can never be changed, and the document id can never be reused. Note that the document may be represented in either XML or JSON and interconverted between these or have its character encoding changed, all the while remaining the same document. However, the directly referenced content within the document and the presentation of the document cannot change substantially (such that it changes the clinical meaning of the content). Any additional documents derived from the same composition SHALL have a different document id. See https://www.hl7.org/fhir/documents.html#content for more details.

# 3.3.2 Use Cases

The following CA:FeX use case leverages this capability:

• UC-01 Create and Submit Document

# 3.3.3 CA:FeX Transactions

This capability describes the FHIR implementation of the CA:FeX Submit Data (CA:FeX-1) transaction found in the Sequence Diagram for UC-01: Create and Submit Document.

# 3.3.4 HTTP Operations

This capability can be leveraged using HTTP POST requests. Implementers are expected to familiarize themselves with how create interactions are executed using the FHIR RESTful API framework.

For more information on the supported HTTP operations, refer to the section CA:FeX Actors and Transactions.

#### **HTTP POST**

A create is executed by performing a POST operation in the RESTful framework:

POST [base]/[type]{?\_format=[mime-type]}

#### **Content Types and Encodings:**

Either application/fhir+json or application/fhir+xml content types are permitted

# 3.3.5 Document Submit Patterns: Fundamental

The simplest method to submit documents is through the submission of the FHIR Document Bundle to a HTTP POST request to a [base]/Bundle endpoint.

This will create the new Bundle resource in a server-assigned location with a server assigned id for the Bundle resource. (*Note: this transaction pattern does not support conditional create which allows the resource to be created only if it does not already exist on the server.*)

Per the FHIR standard on HTTP create interaction:

- The request body SHALL be a valid FHIR Resource (in this case, a FHIR Release 4 Bundle resource)
- The resource does not need to have an id element (this is one of the few cases where a resource exists without an id element). If an id is provided, the server SHALL ignore it.
- If the request body includes a meta, the server SHALL ignore the existing versionId and lastUpdated valu es. The server SHALL populate the id, meta.versionId and meta.lastUpdated with the new correct values
- Servers are allowed to review and alter the other metadata values, but SHOULD refrain from doing so (see metadata description for further information).
- A server SHOULD otherwise accept the resource as submitted when it accepts the create, and return the same content when it is subsequently read. However, some systems might not be able to do this; see the note on transactional integrity for discussion.
- The server returns a 201 Created HTTP status code, and SHALL also return a Location header which contains the new Logical Id and Version Id of the created resource version. See Response Handling for more details.

## **Considerations for Document Submission Using Bundle Endpoints**

Two key attributes of FHIR Documents submitted to the Bundle endpoint are (with limited exceptions):

- Self-contained—All of the primary resources used in the document must be included in the document (see Composition in the FHIR standard); other resources used in the document should also be included.
- Point-in-time—The entire document is stored under the /Bundle endpoint, and the content is not (generally)
  updated. If Data Receiver actor, which supports the /Patient endpoint outside of this transaction, updates an
  address in a Patient resource under /Patient, a Patient resource inside a Document would not be expected to
  reflect that.

**Note:** Despite the fact that a FHIR Document may contain Composition, Patient, Practitioner or other resources, posting a FHIR Document Bundle to a Bundle Endpoint <u>does not make those resources automatically available at their equivalent endpoints</u> (e.g., /Composition, /Patient, /Practitioner, etc.).

- (i) Outside of the scope of this specification's guidance, an implementation may choose to decompose a received FHIR Document, and manage the included resources individually. An implementation that does this should consider several issues, including:
  - Resource deduplication (e.g., when the Patient or Composition resource in a document is actually the same as an already known Patient or Composition resource, perhaps obtained from another document)
  - Sources of truth for various resources and document currency (e.g., whether to update an existing patient address based on a 10-year old document)
  - Whether and how updates to the extracted resources feed back into the submitted document
  - Document lifecycle compared to resource lifecycle (i.e., if a Practitioner resource is removed from the system 5 years after the Practitioner retires, is a FHIR Document or the Composition extracted from it still usable, etc.)
  - Whether to persist the submitted document as well as the extracted resources

# 3.3.6 Document Submit Patterns: Intermediate

The section will evolve in future releases to cover additional submission patterns for documents (e.g., submitting a binary version of the document, performing a bundle transaction, submitting supporting resources that aid in the finding of the document, etc.).

# 3.3.7 Cutting Edge Capabilities

#### **FHIR Operations**

FHIR Operations are used (a) where the server needs to play an active role in formulating the content of the response, not merely return existing information, or (b) where the intended purpose is to cause side effects such as the modification of existing resources, or creation of new resources.

This specification does not currently define any custom operations for the Document Submit Capability. However, a number of operations exist that are actively being tested by the international standards community that can support the creation of a document. These have been listed below for implementers to test and provide feedback on.

Generate a Document Bundle using the \$document Operation - This operation on a Composition (at / Composition/[id]) is helpful for systems that want to generate (and optionally, persist) a document Bundle from an existing Composition, including those that do not retain an original Document used to generate a decomposed Composition.

• Compositions stored at the /Composition endpoint are not FHIR Documents, although the \$document operation may be used to create point-in-time FHIR Documents from a Composition. This operation has been surfaced below but is not an official supported document creation pattern in this release. Feedback from implementers on the use of \$document is requested.

# 3.4 Search for a Document

# 3.4.1 Scope

This capability supports the ability to find documents using parameterized queries.

There are two types of query behavior this capability currently supports.

- Queries that are intended to return a payload that includes any FHIR resources that match the parameters provided. These types of queries combine search and retrieval but put more strain on the requesting system to manage and filter the volume of content in the response in a way that is more manageable to the user.
- Queries that are intended to return a summary of documents that match the parameters provided. These
  types of queries are often coupled with a separate query for retrieval of the documents the requester wants
  to receive.

# 3.4.2 Use Cases

The following CA:FeX use cases leverage this capability:

UC-02 Query and Retrieve Document vRV1

# 3.4.3 CA:FeX Transactions

This capability describes the FHIR implementation of the CA:FeX Search Data (CA:FeX-2) transaction found in the Sequence Diagram for UC-02: Query and Retrieve Document.

# 3.4.4 HTTP Operations

This capability can be leveraged using HTTP GET requests and/or HTTP POST. Implementers are expected to familiarize themselves with how searches are executed using the FHIR RESTful API framework.

See CA:FeX Actors and Transactions for more information on the supported HTTP operations.

#### HTTP GET

In the simplest case, a search is executed by performing a GET operation in the RESTful framework:

GET [base]/[resourcetype]?name=value&...

#### HTTP POST

For this RESTful search (see definition in RESTful API), the parameters are a series of name=[value] pairs encoded in the URL or as an application/x-www-form-urlencoded submission for a POST:

POST [base]/[type]/\_search{?[parameters]{&\_format=[mime-type]}}

# 3.4.5 Considerations for Document Search Patterns

There are two considerations that impact which FHIR resources and search parameters will be used in the HTTP request to return documents.

1) whether the clinical data repository uses FHIR Documents (i.e., Bundle.Composition) <u>exclusively</u> to represent retrievable documents, or if it applies a mixed approach to allow FHIR RESTful retrieval of certain documents in binary.

2) the client and/or server preferences for whether all FHIR resources that meet the search criteria are returned as the response payload in the initial CA:FeX Search Data (CA:FeX-2) transaction.

**Note**: Querying for a CapabilityStatement is a pre-requisite step for implementers that will provide information to the requester on what the responder supports.

Guidance is provided below anticipating that early adopters will likely start with more fundamental patterns of searching for FHIR Documents before expanding their capabilities to perform more nuanced queries as their needs evolve to exchange documents in more sophisticated ways. One known evolution in this regard, is the departure from supporting only FHIR-assembled documents to supporting a hybrid model that can retrieve FHIR Documents alongside documents in legacy formats (e.g., Binary). This evolution requires a different pattern to be applied. These patterns are differentiated below using an enumerated convention (e.g., 2A, 2B).

# 3.4.6 Document Search Patterns: Fundamental

#### CA:FeX-2A (Search Against FHIR Assembled Documents Repository)

The simplest method to search for a FHIR Documents is to construct a query (using the parameters identified below) and to submit that query to a [base]/Bundle endpoint using a HTTP GET or POST command.

This will execute a search which will return the results in the HTTP response as a searchset Bundle containing any document Bundle resources that match the criteria of the search. While the endpoint is anchored around Bundle, the expectation is that composition will be included as a base search parameter to narrow the search to FHIR Documents.

Per the FHIR standard on HTTP search interaction:

- Because of the way that some user agents and proxies treat GET and POST requests, in addition to the get based search method servers that support *search* SHALL also support a POST based search
- Supporting GET means that PHI (Personal health information) might appear in search parameters, and therefore in HTTP logs. For this reason logs should be regarded as being as sensitive as the resources themselves. This is a general requirement irrespective of the use of GET see the FHIR security page for further commentary.
- If the search succeeds, the server SHALL return a 200 OK HTTP status code and the return content SHALL be a Bundle with type = searchset containing the results of the search as a collection of zero or more resources in a defined order.
  - Note that resources returned in the search bundle MAY be located on another server than the one that performs the search (i.e. the Bundle.entry.fullUrl may be different to the [base] from the search URL)
- If the search fails (cannot be executed, not that there are no matches), the return value return value SHALL be a status code 4xx or 5xx with an OperationOutcome. See Response Handling.

## **Considerations for Document Search Using Bundle Endpoints**

Anchoring searches around Bundle in this search pattern is recommended for implementers that want to retrieve <u>all the FHIR resources</u> for any FHIR Documents that meet their search criteria.

- Implementers that use this approach should consider using a combination of search parameters to reduce the processing load on responders and requesters.
- The result collection can be long, so servers may use paging. If they do, they SHALL use the method described here for breaking the collection into pages if appropriate.

This search pattern does not separate the act of search from retrieval. Clients that want to provide their users the ability to review high level information (lists, summaries, etc.) for matching documents to support selective retrieval of the desired FHIR Document bundles will need to utilize different search patterns or manage this behavior in the client's user interface.

(i) Note: Due to limitations in querying for discrete resources when the document is loaded as a FHIR Document bundle, performing searches against Composition or other contained resources (e.g., using Patient resource id) will only work for repositories that a) decompose the resources within the submitted bundles, or b) enable the submission of the contents of the document at their individual endpoints or through a transaction bundle so that they might be retrievable. This approach requires significant caution - implementers should be well versed in the Document Handling Obligations before considering either approach. Guidance on both mechanisms is outside the scope of this specification.

# 3.4.7 Document Search Patterns: Intermediate

#### CA:FeX-2B (Search Against Hybrid Documents Repository)

Implementers are encouraged to incorporate search patterns that allow for more comprehensive support for both FHIR-assembled and FHIR-enabled documents.

Industry-leading implementations like the US Core and International Patient Access (IPA) are promoting the use of resources like DocumentReference to offer implementers a single way to return pointers to document content, wherever it is stored and irrespective of the format (e.g., binary or FHIR-assembled).

This pattern anchors searches around [base]/DocumentReference using the HTTP GET or POST command.

In this pattern, DocumentReference acts as a metadata shell that provides additional information (beyond Composition elements) that supports finding of desired document(s).

This pattern will be fleshed out further in future releases.

## **Considerations for Document Search Using DocumentReference Endpoints**

This pattern provides an effective option to implementers who would prefer to retrieve a list of potential documents without having to retrieve the documents in their entirety. However, use of DocumentReference is <u>not</u> <u>limited</u> to this use case and can return FHIR Binary resources in the attachment content.

While not in the current scope of this specification, parameters like \_include are currently being used by some implementations to return the referenced FHIR resources alongside the DocumentReference.

Implementations like US Core are also actively testing the use of \$docRef operation to support the generation of DocumentReference resources on-the-fly to support a single method of query in sources that may not have DocumentReferences for the desired FHIR Documents. See Cutting Edge Capabilities section below.

# 3.4.8 Document Search Patterns: Supported Search Parameters

The following search parameters are used generically to support document retrieval. *These will continue to evolve as new use cases and requirements are identified.* 

Additional search parameters that are specific to the requirements for a specific use case or IGuide may be further defined by those implementations. See *Option 2 - FHIR Health Information Exchange (HIE) Pattern Using CA:FeX* in the pan-Canadian Patient Summary (PS-CA) Specification for details and examples of how the parameters below are used to retrieve patient summaries.

| Query Search Parameters | Applied to  | Description  |
|-------------------------|---|--|
| composition             | bundle.composition  | This parameter, of type reference, specifies the first<br>resource in the bundle, if the bundle type is<br>"document" - this is a composition, and this<br>parameter provides access to search its contents<br>using chaining. See FHIR Chaining Parameters<br>search methodology. |
| timestamp               | bundle.timestamp  | This parameter, of type date, specifies the timestamp when the FHIR bundle was created. See FHIR http://hl7.org/fhir/R4/search.html#date for use of the date search type.  |
| patient.identifier      | bundle.composition.patie<br>nt.identifier<br>documentReference.patie<br>nt.identifier | This parameter, of type token, specifies an identifier<br>associated with the patient to which the document<br>is assigned. This use of patient.identifier follows the<br>FHIR Chaining Parameters search methodology.   |
| type                    | bundle.composition.type<br>documentReference.type                                     | This parameter, of type token, specifies the kind of<br>document (LOINC if possible). The use of<br>bundle.composition.type follows the FHIR Chaining<br>Parameters search methodology, whereas type can<br>be applied directly in documentReference<br>searches.                  |
| author                  | bundle.composition.auth<br>or<br>documentReference.auth<br>or                         | This parameter, of type reference, specifies who<br>and/or what authored the document. The use of<br>bundle.composition.author follows the FHIR<br>Chaining Parameters search methodology, whereas<br>author can be applied directly in<br>documentReference searches.             |
| date                    | bundle.composition.date<br>documentReference.date                                     | This parameter, of type date, specifies when this<br>document reference was created. The use of<br>bundle.composition.date follows the FHIR Chaining<br>Parameters search methodology, whereas date can<br>be applied directly in documentReference<br>searches.                   |

# 3.4.9 Cutting Edge Capabilities

## **FHIR Operations**

FHIR Operations are used (a) where the server needs to play an active role in formulating the content of the response, not merely return existing information, or (b) where the intended purpose is to cause side effects such as the modification of existing resources, or creation of new resources.

This specification does not currently define any custom operations for the Search for a Document Capability. However, a number of existing operations exist that can support the search for a document. These have been listed below for implementers to test and provide feedback on.

#### Return the Latest Summary for a Patient

This operation is being tested by IPS, for Patient Summary documents, but could be applied generically for other types of documents. The operation asks for the latest appropriate summary, whether that already exists, or must be newly generated. Unless otherwise specified, the server has discretion to choose how to fulfill the request.

#### Generate a Document Bundle using \$document Operation

This operation is particularly helpful for systems that are not persisting the document Bundle that houses the Composition and its referenced resources.

#### Fetch Document Reference using \$docref Operation

This operation is most helpful for implementers using DocumentReference as a primary method for querying for a list of documents and information about their format (binary, composition, etc.) and endpoint (See DocumentReference resource). This operation is used by US Core and International Patient Access implementations. It is primarily used to find or generate a bundle containing the DocumentReference resources that meet the specified parameters.

# 3.5 Retrieve a Document

## Scope

This capability supports the ability to retrieve known documents using the document's resource id.

# 3.5.1 Use Cases

The following CA:FeX use cases leverage this capability:

• UC-02 Query and Retrieve Document

# 3.5.2 CA:FeX Transactions

This capability describes the FHIR implementation of the CA:FeX Retrieve Data (CA:FeX-3) transaction found in the Sequence Diagram for UC:02: Query and Retrieve Document.

# 3.5.3 HTTP Operations

This capability can be leveraged using HTTP GET requests. Implementers are expected to familiarize themselves with how searches are executed using the FHIR RESTful API framework.

See CA:FeX Actors and Transactions for more information on the supported HTTP operations.

#### HTTP GET

In the simplest case, a retrieve is executed by performing a GET operation in the RESTful framework:

GET [base]/[resourcetype]/id

# 3.5.4 Considerations for Document Search Patterns

This pattern is predicated on the requestor knowing the id of the resource they are attempting to retrieve.

Depending on the maturity and scope of the repository, the endpoints supported may be isolated to [base] / Bundle but the repository could potentially support additional document formats which would be retrieved from different endpoints.

**Note**: Querying for a CapabilityStatement is a pre-requisite step for implementers that will provide information to the requester on what the responder supports.

Guidance is provided below anticipating that early adopters will likely start with more fundamental patterns of storing/retrieving FHIR Documents before expanding their capabilities to support the exchange of documents in various formats. One known evolution in this regard, is the departure from supporting only FHIR-assembled documents to supporting a hybrid model that supports FHIR Documents alongside documents in legacy formats (e.g., Binary). This evolution requires a different pattern to be applied. These patterns are differentiated below using an enumerated convention (e.g., 3A, 3B).

# 3.5.5 Document Retrieve Patterns: Fundamental

#### CA:FeX-3A (Retrieve Document From FHIR Assembled Documents Repository)

📥 Canada Health Infoway

The simplest method to retrieve a FHIR Document is to perform a read interaction using HTTP GET [base]/[type]/ [resource id] against a [base] / Bundle endpoint.

Per the FHIR Standard on the HTTP read interaction:

- This returns a single instance with the content specified for the resource type
- This url may be accessed by a browser.
- The possible values for the Logical Id ("id") itself are described in the id type.
- The returned resource SHALL have an id element with a value that is the [id].

## **Considerations for Document Retrieve Using Bundle Endpoints**

Anchoring retrievals around a Bundle endpoint in this retrieval pattern is recommended for implementers that want to retrieve the FHIR Document using the known id for the Bundle. This retrieval pattern is expected to be used by implementers re-retrieving a Bundle that was previously identified in a search/or prior retrieval.

## 3.5.6 Document Retrieve Patterns: Intermediate

#### CA:FeX-3B (Retrieve Document from Hybrid Documents Repository)

Implementers are encouraged to incorporate patterns that allow for more comprehensive support for both FHIRassembled and FHIR-enabled documents. Implementer that extend their capabilities can subsequently expect to support retrieval of documents using additional FHIR endpoints.

This pattern anchors retrieval around [base]/DocumentReference and/or[base]/Binary endpoints using the HTTP GET command.

Anchoring retrievals around a DocumentReference endpoint in this retrieval pattern is recommended for implementers that know the document they are retrieving is an embedded attachment in DocumentReference.

Anchoring retrievals around a Binary endpoint in this retrieval pattern is recommended for implementers that know the document that they are retrieving is a Binary resource. This retrieval pattern is expected to follow a CA:FeX Search Against Hybrid Documents Repository (CA:FeX-2B), if the attachment.url identifies the document can be retrieved from a FHIR Binary endpoint.

This pattern is anticipated to be further fleshed out as use cases requiring this pattern arise.

# 3.5.7 Document Retrieve Patterns: Supported Retrieval Parameters

The following examples are used to retrieve documents based on a known resource ID.

GET [base]/Bundle/[id]

GET [base]/DocumentReference/[id]

GET [base]/Binary/[id]

# 3.5.8 Cutting Edge Capabilities

#### **FHIR Operations**

FHIR Operations are used (a) where the server needs to play an active role in formulating the content of the response, not merely return existing information, or (b) where the intended purpose is to cause side effects such as the modification of existing resources, or creation of new resources.

This specification does not currently define any custom operations for the Retrieve for a Document Capability. Unlike Submit a Document and Search for a Document capabilities, there are no existing operations that this specification has identified that directly impact retrieval of a document resources using resource id.

# 3.6 Response Handling

# 3.6.1 HTTP Status Codes

The HTTP status codes returned in the response aid applications in understanding whether a search was successful, and if not successful, provides some context as to why the search did not return the expected response.

These status codes are considered the base status codes that should be present in any implementing API. Implementations and guides may include additional status codes that their service supports and may supply further details on the circumstances or expected client behavior.

## Error

If the search fails (cannot be executed, not that there are no matches), the return value return value SHALL be a status code 4xx (client error) or 5xx (API/service error). An OperationOutcome SHOULD be returned detailing the error.

| Scenario  | HTTP<br>Status Code                  | Outcome   |
|---|--------------------------------------|---|
| The request is performed with incorrect syntax or against a resource or search parameter that the API does not currently support.   | HTTP 400<br>Bad Request              | Error code is returned in the response with an OperationOutcome detailing the error |
| The request is performed by an application that has not properly authenticated.   | HTTP 401<br>Unauthorize<br>d         | Error code is returned in the response with an OperationOutcome detailing the error |
| The request is performed by an authenticated<br>user, but the authenticated user is not permitted<br>to perform the requested operation.  | HTTP 403<br>Forbidden                | Error code is returned in the response with an OperationOutcome detailing the error |
| The request is performed on a resource type that is not supported   | HTTP 404<br>Not Found                | Error code is returned in the response with an OperationOutcome detailing the error |
| The request is performed using an HTTP method that the server does not support for the resource.  | HTTP 405<br>Method Not<br>Allowed    | Error code is returned in the response with an OperationOutcome detailing the error |
| The request includes a media type which is not<br>supported. For example, the client uploads an<br>image as image/svg+xml, but the server requires<br>that images use a different format. | 415<br>Unsupporte<br>d Media<br>Type | Error code is returned in the response with an OperationOutcome detailing the error |

| Scenario  | HTTP<br>Status Code          | Outcome   |
|---|------------------------------|---|
| The request is performed but the server<br>encountered an internal error during the process<br>of the response message.   | 500 Internal<br>Server Error | Error code is returned in the response with an OperationOutcome detailing the error |
| The request is made when the service is temporarily unavailable.  | 503 Service<br>Unavailable   | Error code is returned in the response with an OperationOutcome detailing the error |
| The request is performed but the server, while<br>acting as a gateway or proxy, does not get a<br>response in time from an upstream server in order<br>to complete the request. | 504 Gateway<br>Timeout       | Error code is returned in the response with an OperationOutcome detailing the error |

#### Success

If the search is properly formatted and succeeds, the API SHALL return an HTTP 200 OK status code and the return content SHALL be a Bundle with type = searchset containing the results of the search as a collection of zero\* or more resources in a defined order.

NOTE: Searches that are properly performed but have no PHI to return will still result in a HTTP 200 OK status code

| Scenario   | HTTP Status<br>Code | Outcome  |
|--|---------------------|--|
| The request is performed with correct syntax and there are FHIR resources available that match those search parameters | HTTP 200 OK         | Success code is returned in the response,<br>Bundle returned in the response contains<br>entries with requested FHIR resources |

# 3.6.2 Operation Outcome

OperationOutcome is used to provide more detailed description of any issues that occurred during execution of an operation. The general conventions for OperationOutcome are:

- OperationOutcome can either be the sole response to an operation (generally accompanying an HTTP code that indicates a failure) or it can be part of a Bundle indicating potential warnings associated with the generation of the search response.
- If an OperationOutcome is returned with anything other than a success (200), the issues it contains will be of type 'error' or 'fatal'. Fatal is used for issues that occur before the query can be exercised, 'error' is used for issues that occur during query execution.
- OperationOutcomes returned as part of a Bundle will only contain 'warning' and 'information' messages. The user should always be made aware of the existence of these messages and the user should have the opportunity to review all such messages.
- The OperationOutcome.issue.code provides a standardized description of the issue. Systems MAY create logic based on the specific code returned.
- The details of the issue or warning will be found in issue.details.text. This content should always be displayed to the user.

- The issue.details.coding values, issue.diagnostics and issue.location are intended for diagnostic purposes and will generally only be relevant to help-desk personnel. It may be appropriate to make access to this information available only by clicking on a button rather than displaying information to the user that may be confusing.
- issue.location will only occur if the problem is with a submitted FHIR instance (i.e. it will not be present if the issue is for query parameters, HTTP headers, etc.). It will be expressed as an XPath regardless of whether the submitted content is XML or JSON.

# 4 Reference Architecture

# 4.1 Purpose

This Reference Architecture provides guidance on how to apply CA:FeX implementation patterns along with other IHE profiles to address interoperability needs pertaining to FHIR Health Information Exchange (HIE) implementation pattern. It defines the rules of engagement and defines the interoperability landscape as well as developing a connectivity platform to allow external vendors to test solutions.

# 4.2 Intended Audience

The intended audience of this Reference Architecture includes, but is not limited, to the following:

- IT departments of healthcare institutions (technical product managers, IT managers, operations staff)
- Technical staff of clinical solution vendors
- Experts involved in standards development
- Individuals and teams responsible for implementing software solutions such as project managers, CTOs, CISOs, software engineers, technical product managers, IT managers, operations staff, and other similar roles.

# 4.3 Overview

This section contains a list of recommended IHE candidate profiles that can potentially be grouped with CA:FeX that can meet specific needs for FHIR Health Information Exchange (HIE) implementation pattern. The sequence diagrams included in this section group together actors and transactions from multiple profiles including CA:FeX to address the scope of the use cases.

# 4.4 How To Read The Reference Architecture

- This document lists actors and transactions from candidate IHE profiles that can potentially be grouped with the CA:FeX Interoperability Specification and enable FHIR Health Information Exchange (HIE) implementation patterns.
- The relationship between consuming and recipient actors are indicated by black lines.
- There are two swim lanes that group together the actors and transactions: Clinical systems and Jurisdictional systems. It is assumed that vendors will take on roles from the clinical systems while provinces and territories will take on roles from the jurisdictional systems.
  - Dark green actors are required actors showcasing different roles within the clinical systems that are required for this release
  - Light green actors are optional actors showcasing different roles within the clinical systems that are optional for this release
  - Dark blue actors are required actors showcasing different roles within the jurisdictional systems that are required for this release
  - Light blue actors are optional actors showcasing different roles within the jurisdictional systems that are optional for this release
- The black lines are the interactions and standardized transactions of the actors and their association with one another as defined by the IHE methodology framework.
- A list of all the IHE profiles are included at the bottom of the Reference Architecture.
- A list of pan-Canadian Profiles are listed at the bottom of the Reference Architecture.

• A legend is found at the bottom of the Reference Architecture to help readers orient themselves to the diagram.

# 4.5 How To Use The Reference Architecture

The list below summarizes how to use this document:

- **Role Identification**: Jurisdictions and vendors will need to identify their role (e.g. actors) from the Reference Architecture and sequence diagrams for each of the use cases in scope.
- **Gap Identification**: Based on the role(s) identified from the Reference Architecture and sequence diagrams, potential assessment is needed for identification of gaps for meeting the requirements of the standardized actors and transactions needed to satisfy particular use cases.
- **Provincial Reference Architecture**: Provinces and jurisdictions may need to draft their own version of Reference Architecture specific to their needs. Current technology landscape, existing architecture and current business priorities will help in developing a version for the province.
- **Document Evolution and Feedback**: This is a living document and will evolve based on feedback and refinements to the the CA:FeX Interoperability Specifications and related use cases. This document is published on InfoScribe to capture comments and feedback from all key stakeholders. Additionally, multiple sessions will be conducted to discuss and update the content of this document.
- Vendor Conformance Testing (Connectation / Projectation): This document will provide an opportunity for vendors to prepare for conformance testing of the CA:FeX Interoperability Specifications on the IHE Gazelle platform. IHE Gazelle is an open-source, web-based test platform supporting a wide portfolio of interoperability test tools suited to validate interface conformity to IHE Profiles and project-specific standards-based interoperability specifications. Vendors can validate their products and eHealth projects to procure interfaces they deploy. For additional information on Gazelle, please refer to the following link: IHE Gazelle

\*Note: It's expected that the reader should have a moderate degree of familiarity with IHE profiles, esp. ATNA, CT and IUA.

# 4.6 High Level View - Reference Architecture for CA:FeX

This is a high-level view of relevant IHE Integration Profiles to support the FHIR HIE implementation using CA:FeX. Required and optional capability support is described in the sequence diagrams associated with each Use Case analysis. Vendors or jurisdictions may decide not to implement optional IHE profiles showcased below, however it is highly recommended that areas pertaining to authentication, auditing and security are being addressed using solutions that currently exist in their respective enterprise architecture.

# 4.7 Foundational IHE Profiles

#### Background

Foundational IHE Profiles address critical interoperability issues such as user authorization (e.g., IUA), security node and audit records (e.g., ATNA) and consistent time (e.g., CT).

#### Assumption

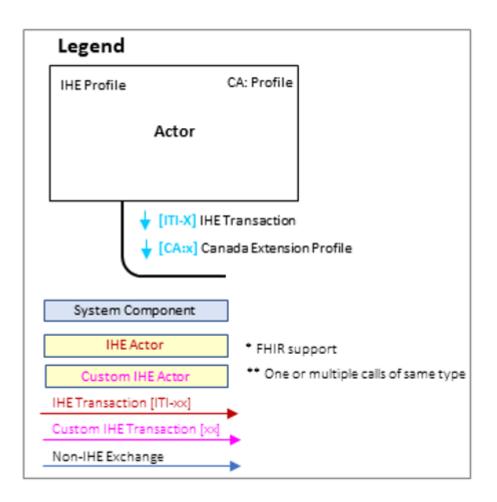

Vendors and jurisdictions in the ecosystem can optionally choose to play the standardized actors and transactions listed in the Foundational Profiles to support implementation of the CA:FeX and to address authentication, auditing and security needs. Additional information and requirements for these Foundational Profiles can be found below. Vendors or jurisdictions may decide not to implement optional IHE profiles listed below, however it is highly recommended that areas pertaining to authentication, auditing and security are addressed using solutions that currently exist in their respective enterprise architecture.

#### IHE Profiles Profiles included: IUA, ATNA, CT

#### Legend

The following diagram is the legend for the sequence diagrams to help readers orient themselves with the diagrams.

## <u>IUA\*</u>

The IUA\* (Internet User Authorization) provides support for authorization to access resources when using HTTP RESTful transports, by managing authorization tokens.

The Authorization Client must have a valid token that must be presented to resource server with every request:

- Get Access Token [ITI-71] performed when Client does not yet have a token or when token is expired
- Incorporate Access Token [ITI-72] the client must include the token with every request
- Introspect Token [ITI-102] the resource server must introspect token at every request

#### ATNA\*

ATNA\* (Audit Trail and Node Authentication) provides support for ensuring that that the communicating systems have a level of trust in each other through node authentication, that communications between the different system components are encrypted (via TLS), and that system activity is audited.

• ATNA\* Authenticate Node [ITI-19]

Before establishing secure communication, mutual authentication is performed between two secure nodes. A secure pipe will be established through which secure transactions will take place.

Secure Node also authenticates the identity of the user who requests access to the node.

• ATNA\* Record Audit Event [ITI-20]

The Secure Node/App sends auditable events to an Audit Record Repository. The triggers for sending audit logs can vary and may be specified in other IHE profiles, local law or regulation, or local policy.

| ATNA*<br>Secure Node/App          | ATNA*<br>Secure Node (Remote) | ATNA*<br>Audit Record<br>Repository | ATNA* |

## <u>CT</u>

CT (Consistent Time) ensures that the system clocks and time stamps of the many computers in a network are well synchronized. Synchronization with a median error less than 1 second is sufficient for most purposes.

# 4.8 Sequence Diagram for UC-01: Create and Submit Document

Scenario: Clinical Solution A Retrieves Document from a Central Clinical Data Repository

#### Assumption: Document is stored in a Clinical Data Repository

This sequence diagram provides the option of using the CA:FeX Interoperability Specifications that provide support for saving and retrieving data (e.g., documents) to and from a central Clinical Data Repository. This specification includes a Data Source and a Data Recipient actor. Additionally, this sequence diagram uses the 'Submit Data' FHIR operation.

#### Sequence Diagram Overview:

Below provides guidance on how to read the sequence diagram:

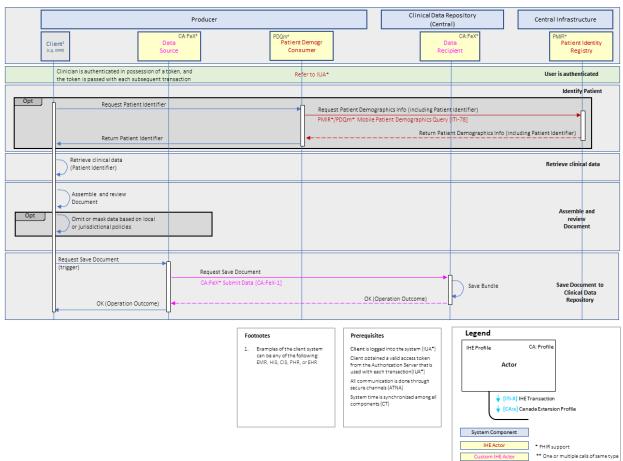

- This sequence diagram illustrates how the different standardized actors of a system should interact with each other to carry out specific standardized transactions, and the order in which the transactions and interactions occur when UC-01 of the CA:FeX Specification is executed.
- The legend on the bottom right corner describes the different system components, actors and transactions that are necessary to carry out this use case.
- The green swim lane is a simplified view of the actors and transactions required by the Foundational IHE Profiles, in addition to the other ones that are not explicitly illustrated on the diagram (e.g., ATNA, CT, etc.) but included as a white note. These are pre-requisite conditions for this use case and it is assumed that these will be satisfied.
- The blue swim lanes groups a sequence of processes (along with their required actors and transactions) that are needed to occur to satisfy this use case. These are to be read from left to right and top to bottom.
- The red note boxes describe important information and notes that provide more context for the sequence diagram.
- More information about the details of the Foundational IHE Profiles can be found in the PS-CA Specifications available here.

#### **Additional Considerations**

The sequence diagrams included in this section do not showcase all of the possible combinations of IHE profiles and transactions that can be used for a particular implementation pattern. For example, ITI-83 transaction can be used in place of ITI-78 if the preferred implementation pattern is PIXm/PMIR.

IHE Transaction [ITI-xx] Non-IHE Exchange

#### UC-01: Create and Submit Document - CA:FeX

# 4.9 Sequence Diagram for UC:02: Query and Retrieve Document

**Scenario:** Clinical Solution A Retrieves Clinical Data from a Clinical Data Repository.

#### Assumption: Clinical Data is stored in a Central Clinical Data Repository

This sequence diagram provides the option of using the CA:FeX Interoperability Specifications that provide support for saving and retrieving data (e.g. documents) to and from a central Clinical Data Repository. This specification includes a Data Consumer and a Data Responder actor. Additionally, this sequence diagram uses the 'Search Data' and 'Retrieve Data' FHIR operations.

#### Sequence Diagram Overview:

Below provides guidance on how to read the sequence diagram:

- This sequence diagram illustrates how the different standardized actors of system should interact with each other to carry out specific standardized transactions, and the order in which the transactions and interactions occur when Use Case 2 of the CA:FeX Specification is executed.
- Data Consumer role varies by client type:
  - HCP: Clinical Solution, e.g., EMR used by the Health Care Provider to request & retrieve access to clinical document(s) from the Clinical Data Repository
  - Patient: Patient Portal used by the Patient / Subject of Care to request & retrieve access to their clinical document(s) from the Clinical Data Repository
- The legend on the bottom right corner describes the different system components, actors and transactions that are necessary to carry out this particular use case.
- The green swim lane is a simplified view of the actors and transactions required by the Foundational IHE Profiles, in addition to the other ones that are not explicitly illustrated on the diagram (e.g. ATNA, CT) but included as a white note. These are pre-requisite conditions for this particular use case and it is assumed that these will be satisfied.
- The blue swim lanes groups sequence of processes (along with their required actors and transactions) that are needed to occur to satisfy this particular use case. These are to be read from left to right and top to bottom.
- The red note boxes describe important call outs, information and notes that provide more context for the sequence diagram.
- More information about those details of the Foundational IHE Profiles can be found in the PS-CA Specifications available here.

# 4.9.1 Additional Considerations

The sequence diagrams included in this section do not showcase all of the possible combinations of IHE profiles and transactions that can be used for a particular implementation pattern. For example, ITI-83 transaction can be used in place of ITI-78 if the preferred implementation pattern is PIXm/PMIR.
